TITLE:

The Optimum Quantization Threshold of the Received Signal for Binary Detection Systems

PERIODICAL:

- Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika, 1959, Vol 2, Nr 3, pp 292-298 (USSR)

ABSTRACT:

The problem of selecting the optimum position of the threshold with binary quantization is solved by means of the maximum criterion of the information amount of the useful signal contained in a quantized signal. Citing five foreign papers, the author in a review also approaches to the binary quantization problem. He mentions also the papers of V.A. Garmash (Ref.7) and A.Ye. Basharinov, B.S. Pleyshman (Ref.6). The paper of the latter was presented at a scientific session of these authors in Moscow on Radio Day 1958, whereby the approach of the author states that in most to that of H. Blasbalg (Ref.5). The author states that in most papers different and somewhat arbitrary optimum criterions were used which are not in agreement with each other. He states that the theoretical information approach to this problem produces a

Card 1/3

APPROVED FOR RELEASE

**The Optimum Quantization Threshold of the Received Signal for Binary Detection Systems**

very clear formulation of the problem, a natural criterion and a simple solution. The author then discusses quantization as an information conversion, during coherent and incoherent reception. Finally, the author states that the optimum solution of a problem is only relative: using different optimum criteria will result in different optimum solutions of one and the same problem. It is unessential which of these solutions is better, since each solution is the best in regard to its criterion. These differences are caused primarily because the phenomenon under consideration has not been completely explained as yet. In the papers of A.N. Kolmogorov, N. Viner, V.A. Kotel'nikov, K Shannon, V.I. Siforov, A.A. Kharkevich and others, the informational nature of the communication process was established. These papers should be used for formulating the problem of the degree of agreement between the criteria. The problem of detecting a signal in noises belongs to the class of problems of extracting from the signal received the information of the actual state of the useful signal, i.e. it is

Card 2/3

05196

TEXT: The process of reception is divided basically into two stages: 1) Signal conversion with the purpose of preparing the solution and, 2) adoption of a solution. As one of the optimum methods of signal pre-treatment, it is possible to use calculation of the differences of the existing amounts of information about the possible states of the transmitted signal. This leads to the calculation of the logarithm of the probability ratio, thus revealing the information sense of the algorithm operations of the theory of verification of statistical hypotheses. The problem of optimum multi-channel reception is briefly discussed. The second stage, adoption of a solution, is considered as a choice of optimum strategy. It is shown that the number of optimum strategies in a discrete n-alterna-

("Tr. Sibirsk. fiz.-tekhn. in-ta pri Tomskom un-te", 1961,  
no. 40, 18 - 23)

TEXT: The author discusses the question of the criteria which characterize the reception quality of a signal on a noise background. Utilizing the known relations for the distribution laws of the envelope and the phase of the signal and noise superposition, the author calculates the quality of information included in various parameters of the high frequency signal and compares, on that basis, different methods of signal reception. Numerical calculations of information quantities, carried out for different reception methods (amplitude, phase), and different signal/noise ratios lead to the following conclusions: 1) all the information is extracted from the received signal by a coherent detector, if the phase of its heterodyne coincides with the phase of the useful signal; 2) detection through only

Card 1/2

On the content of the useful information in the...

S/058/62/000/008/098/134  
A062/A101

one of the parameters (amplitude or phase) is connected with unavoidable loss of information; 3) at low signal/noise ratios the phase of the received signal is more sensitive than the amplitude to a change in the state of the useful signal; 4) at low signal/noise ratios the complete information is near to the sum of amplitude and phase information. The last fact reflects a weak statistical connection between the amplitude and the phase of the received signal at low signal/noise ratios.

TITLE:

On the problem of the calculation of the probability of the detection of signals from radar stations in the case of a random search law

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika, v.4, no.6, 1961, 666-670

TEXT:

The problem of the detection of radar signals reduces to the problem of coincidence of pulses belonging to two different sequences. In the case when both sequences are periodic and the ratio of the repetition periods is an integer, coincidence of the two sequences never occurs if it does not occur after a time  $(T_1 - T_2)/HCF$ , where HCF is the highest common factor. For ratios of the periods close to an integer the period of coincidence is so great that detection is also practically impossible. In some cases this does not matter but in others when it is required that the probability of detecting any radar station should be different from zero it is essential to use a random search law. The method of calculating the

Card (1/2)

On the problem of the calculation ... S/142/61/004/006/005/017  
E025/E535

probability of detecting a radar station for a random law of search is given. The results can be used to calculate the probability of detection after a single rotation of the antenna or after any period of time after the beginning of the search. The pulses from the radar station to be detected are assumed to be periodic and the detecting pulses to be random. The coincidence interval is the sum of the lengths of one pulse of each system. The probability is calculated that a particular pulse of the random sequence should be within the coincidence interval centred on a particular pulse of the periodic system. Then, by integration, the probability that a particular pulse of the random system should coincide with any pulse of the random system is calculated. The final stage is the calculation of the probability that after a given time a coincidence should occur with any pulse of the first system. The calculations are carried out for the particular case of a probability density distribution of the random sequence given by a negative exponential.

TITLE:

A method for optimum processing of a received signal if noise  
occurs

PERIODICAL: Radiotekhnika, v. 16, no. 2, 1961, 9-14

TEXT: It is well known that synchronous detecting makes it possible to preserve all useful information, and, therefore, is the optimum demodulator for an amplitude modulated signal with a Gaussian noise. So far, it has not been cleared if there are any other technical methods to process a received signal, which would be as efficient. The present paper tries to solve this problem. The circuit developed does not use the knowledge of the initial phase of the useful signal for phase tuning of the heterodyne, as it is done by synchronous detecting, but for calculating coefficients which occur in the weighted sum of the output signals of two coherent detectors. These detectors are working in "quadrature", i.e., with a 90° phase shift. This circuit is called "quadrature detector". The

Card 1/2

algorithm coefficients of operation of a quadrature detector when taken as a function of  $a$  and  $\theta$ , ( $a$  is the vector length of the useful signal,  $\theta$  is the phase angle) proved to be proportional to the mathematical expectations of the weighted stochastic variables. This fact makes it possible to investigate a self-tuning variation of the quadrature detector which can be operated with an ergodic input signal. Calculations show that this variation initially works as a square-law detector, but as the averaging time of the calculated coefficients increases the detector characteristic is also improving and finally changes over to a synchronous detector characteristic. Constructing such a quadrature detector has the important advantage that the parameters  $a$  and  $\theta$  of the useful signal do not have to be known. TITLE:

Optimum quantization of a received signal at several levels

PERIODICAL:

Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika, v. 5, no. 2, 1962, 273 - 280

TEXT:

The problem of the optimum method of quantizing a received signal which is in the form of a useful discrete signal and continuous noise is analyzed. The signal amplitude can have values  $a_0 = 0$  or  $a_1 = a$ , their probabilities being  $p(a_j)$ , where  $j = 0, 1$ . The received signal  $x$  is mixed with noise and is, in fact, a continuous waveform which is characterized by a random probability distribution function  $p(x/a_j)$ . This signal  $x$  is quantized into  $n$  levels in such a way that a discrete random quantity  $z$ , having  $n$  possible values, corresponds to a continuous random quantity  $x$ ; thus,  $z$  takes a value  $z_i$  if  $x_i \leq x \leq x_{i+1}$ , where  $x_i$  is the

Card 1/3

S/142/62/005/002/019/019  
E192/E382

Optimum quantization ....

$i$ -th quantization threshold. The quantity of information  $I$  contained in the function  $z$  relative to  $a$  is therefore dependent on the position of the quantization levels  $(x_i)$ .

The problem consists of determining the maximum possible information, i.e. finding the solution of the following system of equations:

$$\frac{\partial I}{\partial x_i} = 0, \quad i = 0, 1, \dots, n \quad (2).$$

It is found that a general analytical solution of this system is hardly possible. However, various practical cases can be solved numerically by means of electronic digital computers. This procedure was followed for the case of a multidimensional quantization of a signal received by the non-coherent-reception method. Some of the results of the calculations are shown in Fig. 33, which illustrates the change in the ratio of the

Card 2/3

Optimum quantization ....

S/142/62/005/002/019/019  
E192/E382

quantity on information preserved in a quantized signal to the total information as a function of the number  $n$  of the quantization level for various  $a$ . The figure shows that at small  $a$  the increase in the number of levels considerably reduces the loss of information. Thus, if a receiving system is required only for the purpose of determining the presence or absence of a useful signal in noise, an increase in the number of the quantization levels is justified only if the signal-to-noise ratio is low. There are 3 figures.

ACCESSION NR: AR5006740

where  $\mathcal{L}$  is the ratio of the signal to the noise, and  $t$  is a given value of the random variable  $x$ , is frequently encountered. In the article, all of the approximate formulas for computing  $F(a, t)$  are systematized, and a few new formulas are introduced with an estimate of their convergence. The region of values of parameters in which each formula is applicable is discussed. Tabulations of the function  $F(a, t)$ , calculated on the "Ural" computer are presented. For each  $a$  and  $t$ , one has the expression

$$F(a, t) = 1 - e^{-\frac{a}{t}} \sum_{k=0}^{\infty} \frac{1}{k!} \left(\frac{a}{t}\right)^k \sum_{n=0}^k \frac{1}{n!} \left(\frac{a}{t}\right)^n. \quad (3)$$

The authors introduce the new approximate formula

$$F(a, t) = \frac{e^{-\frac{a}{t}}}{1 - \frac{a}{t}} \left(1 - e^{-\frac{a}{t}} \left(1 - \frac{a}{t}\right)\right) - e^{-\frac{a}{t}} R(a, t). \quad (1)$$

Card 2/3

L 39420-65

ACCESSION NR: AR5006740

Here,  $R(a, c)$  is the remainder term

$$R(a, c) = \sum_{n=0}^{\infty} c_n \int_0^1 x^{a+n-1} dx - \sum_{n=0}^{\infty} c_n \left[ 1 - e^{-\frac{1}{2}} \sum_{k=0}^n \frac{1}{k!} \left(\frac{1}{2}\right)^k \right] \quad (4)$$

where

$$c_n = \frac{(1-\frac{1}{2})^{a+n}}{\Gamma(a+n)} \quad c_0 = \frac{(1-\frac{1}{2})^a}{\Gamma(a)} \quad (5)$$

Formula (1) becomes more accurate, the smaller are  $a$  and  $c$ . A tabulation of  $F(a, c)$  is given to 8 decimal places for  $a = 0, 2 (0, 2) 4$ ;  $c = 0(0, 1) 6$ . V. Barinova.

TITLE: Investigation of an interference-resistant wireless receiver with statistical self-adjustment of the useful signal for the reception of double Markov signals of k-th order in Gaussian noise

CITED SOURCE: Ref. zh. Matematika, Abs. 12V199

TOPIC TAGS: receiver, Markov chain, Markov process, signal reception, noise, Gaussian noise, self adjusting system

TRANSLATION: A receiver of double Markov signals of the k-th order is investigated, when the conditional probability distributions  $p(a_n = 0 | a_{n-1}, \dots, a_{n-k})$ , determining the statistical properties of the signal sequence, are unknown and are determined in the process of reception;  $a_n$  is the n-th double symbol. In this case, for an estimate of the quantity  $p$ , the mean frequency of the occurrence of zero among the symbols  $a_{n-1}, \dots, a_{n-k}$  in a received sequence is derived. If the symbol 0 is realized, the estimate for the probability  $p$  is increased by  $\sqrt{1-p}$ ; in the opposite case it is decreased by  $\sqrt{1-p}$ . The

Card 1/2

L 38598-65

ACCESSION NR: AR5006744

quantity  $\delta$  determines the mobility of the estimate of  $p$ . The level of quantization of the received signal appears optimal according to the information possessed at the given moment about the statistics of the received signal. Thus, an inverse loop is created. The characteristics of a system were determined with the aid of the "Ural" computer. The dependence of errors of the first and second orders on the length of the received sequence was calculated for various values of  $\delta$ , signal to noise ratio and  $k$ . The indicated comparison was carried out with respect to perturbation-stabilizing systems connected with a system not depending on a statistical connection between symbols. The problem of the technical realization of such a system is discussed.

TITLE: Some aspects of the problem of determining the true distribution of radio-luminance in the heavens

SOURCE: IVUZ. Radiofizika, v. 8, no. 3, 1965, 446-452

TOPIC TAGS: radio astronomy, spectral distribution, cosmic radio source

ABSTRACT: <sup>12,55</sup> The author examines the limitations of the integral equation on which most methods for determining the true radioluminance distribution in the sky are based. The appropriate integration time is evaluated for the output signal of a radio telescope such that radio sources of different intensities are detected. The question of analog vs. discrete scanning is treated. The use of physical analog elements instead of complex processing with electronic computers is discussed. In particular, the problem of analysis is reduced to the use of an inverse linear filter through which a signal proportional to the brightness distribution function is passed. The noise characteristics of this system are examined in some detail.

ABSTRACT: Two classes of optimality criteria of the quantization threshold of a received signal, in a detection system, are compared: (a) cost criteria connected with mean-risk minimization and (b) information criteria. The cost approach with the mean-risk minimization solves the problem of optimal threshold in a broader sense; however, this approach comes close to the informational at the decision-making phase. The cost approach may be given an information interpretation; however, from the viewpoint of obtaining maximum information, the equation for optimal quantization threshold differs from the corresponding equation for minimum mean loss. The case of binary quantization of a signal mixed with additive Gaussian noise is analyzed in detail. It is proven that, despite different optimality criteria, the optimal thresholds are close to each other. Two figures. Bibliography of 8 titles. L. S. [Translation of abstract]

 ABSTRACT: The possibility is explored of enhancing the traffic carrying capacity of a Gaussian channel with propagation-ratio fading by means of controlling the transmitter power and channel frequency band; practical physical limitations are allowed for. Within a signal-to-noise ratio of 1--30, the power control can reduce the fading-caused traffic-capacity loss from 17 to 12%; in a lower signal-to-noise ratio range ( $\ll 1$ ), the traffic capacity increases thanks to fading. Also, a case of controlling the coder and channel band, with a constant transmitter power and a specified mean frequency band, is considered. N. S. [Translation of abstract]

TITLE: Influence of Additive Coloration on Electrical Properties of Alkali-Halide Crystals (Vliyaniye additivnogo okrashivaniya na elektricheskiye svoystva shchelochno-galoidnykh kristallov)

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, fizika, 1958, Nr 5, pp 121-126 (USSR)

ABSTRACT: An alkali-halide crystal lattice is postulated in which the density of 'natural' impurities (F-centres, lattice imperfections) is constant, and into which is introduced an additional type of impurity whose concentration varies in a known manner with time. The added impurity atoms are (or become) ionised and contribute to the electrical properties of the lattice. One may associate for example an ionic conductivity  $\sigma_1'$  with the added impurity, which is distinguishable from the ionic conductivity  $\sigma_1$  associated with the F-centres. When a potential difference  $P$  is applied across such a crystal the following relations hold:

$$\frac{dx}{dt} = - \frac{\sigma_1 P}{\sigma_1' + \sigma_2 - \sigma_1} \cdot \frac{1}{E^2} \cdot \frac{dE}{dt} = uE \quad (1)$$

JOV/139-53-5-26/35

Influence of Additive Coloration on Electro-  
Halide Crystals

. Properties of Alkali-

Here  $E$  is the field associated with  $P$ ,  $\sigma_2$  is the electronic conductivity, deriving from the electrons of the added impurity atoms,  $x$  is a measure of the concentration of impurity atoms, and  $u$  is the mobility of the F-centres. The  $\sigma$ 's and  $u$  are related, via the mean free path, to the lattice temperature, and this leads to the following expression for the total current at time  $t$  and temperature  $T$ :

$$I = I_0 I_1 \left[ I_1^2 + (I_0^2 - I_1^2) \frac{t}{T} \right]^{-\frac{1}{2}} \quad (3)$$

where  $I_0$ ,  $I_1$  are respectively the current contributions from the added impurity atoms and the F-centres. If one further denotes the ionic part of  $I_0$  by  $I_{0i}$  (and hence the electronic part by  $I_0 - I_{0i}$ ) then the F-centre concentration may be

Card 2/4

NOV/199-56-5-26/55

Influence of Additive Coloration on Electrical Properties of Alkali-Halide Crystals

expressed in terms of the I's thus:

$$N = \frac{2TI_1}{e v} \cdot \frac{J_0 - J_{01}}{I_0 + I_1} \quad (4)$$

where  $e$  denotes the electronic charge and  $v$  the crystal volume. Hence measurements of the impurity current enable the F-centre concentration to be deduced. Further, measurements of  $\sigma$  at various temperatures and known impurity concentrations enable the F-centre mobility to be determined:

$\log \sigma$  plotted against  $T^{-1}$  gives a straight line whose slope is the mobility. Such curves were plotted from measurements on crystals of KCl, KBr and NaCl, to which impurities had been added, at various temperatures. The effect of the added impurity was to increase the F-centre mobility by a factor varying from about 3 at 600°C to 5 at 450°C. The work was first reported at the Conference of Higher Education Establishments on Dielectrics and Semiconductors at Tomsk, in

TITLE: On the Effect of Coloration Processes on the Electrical Conductivity of Crystals of Alkali Halide Salts

PERIODICAL: Uch. zap. Leningr. gos. ped. in-ta im. A.I. Gertsena, 1958, Vol 148, pp 151 - 169

ABSTRACT: With the aid of a string electrometer and in accordance with the method of constant deflection, the author studied the variations to which the electrical conductivity  $\sigma$  is subject in single crystals of KCl, KBr, and NaCl as a result of coloring and decoloring the samples under a current at constant temperatures. He also studied the temperature dependence of  $\sigma$  and the applicability of Ohm's law to the case of decolored crystals that are colored under a current or in the vapors of an alkali metal. In the 450° to 650°C temperature range a drop in  $\sigma$  as a result of coloration and decoloration was detected in the case of all types of crystals. This attests to the fact that irreversible changes take place in crystals during these processes. The temperature dependence of  $\sigma$  was

Card 1/2

On the Effect of Coloration Processes on the Electrical Conductivity of Crystals of Alkali Halide Salts

studied in the  $250^{\circ}$  to  $650^{\circ}\text{C}$  range. Measurements showed that the magnitude of  $\sigma$ , which drops as a result of coloration and subsequent decoloration, is maintained at various temperatures. In a field range of 100 to 1,500 v/cm Ohm's law is satisfied in decolored and control crystals in the case of rising temperatures. Under certain conditions of the experiment (unidirectional currents, a diverse number of values of the applied voltage) a deviation from Ohm's law can be observed in any sample in the case of falling temperatures. This fact is not connected with characteristics of the decolored condition; it is explained by the effect of high-resistance layers developing near the electrodes in dielectrics that are being formed (RZhFiz, 1956, Nr 1, 1112).

TITLE: A study of the space charge arising with the motion of F centers  
in alkali halide crystals

PERIODICAL: Referativnyy zhurnal, Fizika, no. 6, 1962, 24, abstract 6E204  
("Uch. zap. Kabardino-Balkarsk. un-t", 1961, no. 13, 87-92)

TEXT: The specific conductivities  $\sigma_1$  and  $\sigma_2$ , relating to the decolored zone (existing in the process of the color boundary shift) of a partially colored KCl crystal, and to a completely decolored crystal, respectively, have been confronted experimentally. They do not coincide, and  $\sigma_1$  undergoes considerable variations with the motion of the color boundary, smoothly approaching  $\sigma_2$  at the end of decoloration. Results are explained by the effect of the colored on the non-colored part of the crystal, i.e., by the formation of a space charge at the boundary. ✓

TITLE: The electric properties of alkaline-haloid crystals subjected to coloring from a sharp cathode

PERIODICAL: Referativnyy zhurnal, Fizika, no. 11, 1962, 4, abstract 11-4-7a ("Uch. zap. Leningr. gos. ped. in-ta im. A. I. Gertsena", 1961, 207, 163 - 175)

TEXT: KCl and NaCl samples, grown from a smelt, were used for studying the relation between the currents and the time when introducing in the samples a cloud of color from a sharp cathode, and subsequently eliminating it. Observations were carried out of the velocity and the character of the fore front of the small spreading cloud of the F-centers. The measurements were conducted at temperatures of 450 - 700°C and at voltages of 100 - 1,200 v. Later on, the electric conductivity of the colored and then decolorized crystals was compared to the conductivity of untreated crystals at various temperatures. The investigations revealed that, as a result of coloring, the ionic conductivity of the

The electric properties of...

S/058/62/000/011/049/161

A160/A101

crystals irreversibly decreases, the intensity of the cloud diminishes, and that its motion velocity increases. It is assumed that the conductivity of the colored crystal is caused by the interaction of two types of current carriers, the ions and the electrons, and that it does not represent a plain total of an invariable electrolytic and induced electron conductivity. There are 15 references.

TOPIC TAGS: potassium chloride crystal, electric conductivity, effect of cadmium impurity, electrolytic coloring, thermal coloring, color cloud

TRANSLATION: A comparison investigation is made of the electric conductivity  $\sigma$  and of the electrolytic coloring of KCl-Cd crystals and pure specimens at temperatures (T) above 300°C. The low tem-

Card 1/2

ACCESSION NR: AR4032179

perature conductivity in KCl-Cd is much lower than in the pure specimens. From the  $\ln \sigma \sim T^{-1}$  relation it follows that the mechanism of conductivity at high and low temperatures is the same. At room temperature  $\sigma = 10^{-25} \text{ ohm}^{-1} \text{ cm}^{-1}$ . Thermal coloring in KCl-Cd in contact with sodium begins at higher temperatures than in pure specimens, and proceeds much more slowly. The color cloud in mixed crystals has a high intensity which depends little on T, and is practically stationary in the electric field. The "current-time" curves plotted as the color cloud moves in KCl-Cd are not monotonic. It is assumed that the colored cloud is colloidal sodium. Suggestions are advanced with respect to the mechanism of the processes. V. S.

TITLE: Some data on the electric conductivity of KCl crystal irradiated by light of an aluminum spark at high temperatures

CITED SOURCE: Uch. zap. Kabardino-Balkarsk. un-t, vy\*p. 16, 1962, 272-278

TOPIC TAGS: Potassium chloride crystal, electric conductivity, aluminum arc irradiation

TRANSLATION: The electric conductivity of single-crystal KCl with Pt electrodes was measured prior to irradiation, during the course of irradiation with a condensed Al-spark, and after cessation of the irradiation, in fields of 50--100 V/cm at temperatures 270--540°C. Freshly grown crystals, additively colored and discolored, were investigated. Depending on the intensity of the irradiation, the conductivity was either increased or decreased by the radiation, and when the air layer between the spark and the crystal was 1.5--2 cm thick, only weakly pulsating

Card 1/2

L 16189-63

ACCESSION NR: AR3005165

0

currents were observed. The decrease in the conductivity is a process that is reversible in time, and the conductivity increase obtained during the irradiation is conserved to a considerable degree after the cessation of the irradiation. Curves are presented for the time variation of the current flowing through the crystal, before and after the irradiation. It is assumed that when the crystal is irradiated two processes occur simultaneously: 1) the anion vacancies capture the electrons released as a result of irradiation, causing an increase in the number of free cation vacancies and a decrease in the crystal conductivity, and 2) the metastable levels of the electrons released by the radiation and by the thermal motion from the regular anions and negative ions of the impurity become attached to the positive ions of the impurities; this leads to a decrease in the number of the ordinary current carriers in the crystal and a drop in its conductivity. The first or second process may predominate, depending on the experimental conditions. A. Poletayev.

CONCLUSIONS: The article summarizes results of research work on sociological aspects of the environment for sustainable development.

these alloys. The microstructure and some experimental studies of titanium alloys containing titanium, zirconium or niobium are analyzed along with the effect of oxygen, hydrogen and heat treatments on alloy structure and properties. The tendency of titanium alloys to embrittlement as a result of oxygen aging is explained, and the effect of titanium, zirconium or niobium on the structure and properties of titanium alloys is discussed. The effect of heat treatments on the properties of titanium alloys is explained, and the effect of titanium, zirconium or niobium on the properties of titanium alloys is discussed. The effect of heat treatments on the properties of titanium alloys is explained, and the effect of titanium, zirconium or niobium on the properties of titanium alloys is discussed.

ABSTRACT: Previous studies have shown the critical concentration for the  $\beta$ -solid solution of another element in titanium to be between 6 and 9%, and that the most stable of these combinations are formed by rhenium, nickel, molybdenum, and tungsten. Recently, there has been much interest in multicomponent alloys with the metastable  $\beta$ -structure, which have high technological versatility when hardened. For these and other reasons the authors decided to study the Ti-Mo-Fe-Cr-Al system, both in its  $\beta$ -phase and with an eye to choosing alloys for more detailed experimentation. The samples chosen for experimentation had molybdenum in concentrations of wt. 2-8%, chromium from 4-9%, iron from 3-8%, titanium from 81-113%.

and aluminum constant at 3%. All samples but one were held at 200C for 100 hours, and that one was held at 200C for 9 hours. Two samples were also held at 300C for 100 hours; all the remaining samples disintegrated. Four of them disintegrated with the precipitation of the  $\omega$ -phase, which lasted 100 hours longer; the others disintegrated with the precipitation of the  $\alpha$ -phase. Samples which had 2 and 5% Mo did not depend, for the stability of their properties, on the corresponding amounts of chromium and iron within the limits studied. The samples with 2% Mo had amounts of chromium decreasing from 9.07 to 3.76% while the iron increased from 2.8 to 7.3%; the amount of chromium in samples with 5% Mo decreased from 9.40 to 4.08% while the amount of iron increased from 3.04 to 5%. In samples containing up to 5% each of iron and chromium, 1 or 2% more than 5% Mo did not significantly increase the stability of the  $\beta$ -alloy, and the delay in the process of disintegration is hardly worth the cost. Orig. art. has: 2 tables, 23 graphs, 11 photomicrographs, and 4 roentgenograms.

TITLE: Dislocations in the titanium - molybdenum - iron - aluminum alloys

SOURCE: AN SSSR. Doklady\*, v. 156, no. 4, 1964, 789-791, and insert facing p. 790

TOPIC TAGS: alloy dislocation, Ti Mo Fe Al, alloy, chilled alloy microstructure,  
etching, electromicroscopic study

ABSTRACT: By analyzing the structure of a quenched  $\beta$  - alloy of Ti - Mo - Fe - Al, the authors have found precipitations having the appearance of "sticks". Similar "sticks" were found earlier in quickly chilled Ti - 10% Mo alloys by T. H. Schofield et al. (Acta Metallurgica 7, no. 6, 403, 1959) who described them as regular arrays of etch holes caused by unstable groups of dislocations which are changed during cooling into a stabler net of subgrains. X-ray diffraction patterns obtained by the present authors show no presence of a new phase such as titanium hydride. It is pointed out that dislocations which are present in all metals, become apparent only under favorable conditions of etching. Electromicroscopic study of the "sticks" has actually demonstrated that they are formed by a series of little

ABSTRACT: Alloy VT15 of the system Ti-Al-Cr-Mo, containing 3% Al, 11.5% Cr, and 7% Mo, was quenched from 800C and aged under various conditions, then subjected to x-ray powder analysis. Aging was found to be associated with (1) a marked change in the chemical composition of the  $\beta$  phase, (2) distortion of its crystal lattice, and (3) precipitation of the  $\alpha$  phase. The aging process occurred at the same rate after quenching in water and after quenching in air. The precipitation of the  $\alpha$  phase causes an increase in ultimate strength and a corresponding decrease in plasticity. Alloy VT15

Card 1/2

L 45429-65

ACCESSION NR: AT5011354

has high mechanical characteristics after quenching from 760-800C in air and aging at 450-480C for 25-50 hrs. This is due to the two-phase structure of this alloy. In the course of aging, the alloy matrix ( $\beta$  phase) becomes enriched with the alloying elements (chromium and molybdenum), and thus its thermal stability improves. Hardening of the  $\beta$  phase is increased by the distortion of its crystal lattice when the disperse particles of the  $\alpha'$  phase precipitate. These particles have an inhibiting effect on the development of plastic deformation. Orig. art. has: 1 figure and 2 tables.

TITLE: Hot hardness in 8 alloys of the Ti-Mo-Cr-Fe-Al system

SOURCE: AN SSSR. Izvestiya. Metally, no. 2, 1965, 141-146

TOPIC TAGS: titanium alloy, molybdenum alloy, chromium alloy, aluminum alloy,  
iron alloy, metal mechanical property

ABSTRACT: Hot hardness measurements on six Ti-Mo-Cr-Fe-Al alloys gave a preliminary idea of the over-all high temperature strength properties. Measurements were in the 20-1000°C range (after holding for one minute) and hardness versus time plots (1, 5, 15, 30 minutes) were also obtained at 20, 500, and 800°C under a load of 1 Kg. Differences in positions of maximum hardness for the forged at 1000°C but not reheated to 700°C specimens is said to be caused by the different amounts of segregations. Alloy compositions used had somewhat varying compositions. Non heat-treated (forged) alloys maintained a higher hot hardness than heat treated al-

Card 1/2

L 55852-65

ACCESSION NR: AP5013117

loys, i.e. hardness at 600°C was about the same as room temperature. A sharp drop is noticed after 700°C. The 700°C reheat does not provide enough time for the attainment of equilibrium conditions. A truer picture of  $\beta$  precipitation would be attained with longer annealing time under vacuum. Hardness versus time curves sometimes show slight rises with increasing time due to precipitation of  $\beta$ . High temperature hardness in the 20-600°C range indicated effectual high temperature strengthening. Orig. art. has: 2 figures, 1 table.

TITLE: Aging of  $\beta$ -alloys in the Ti-Mo-Cr-Fe-Al system

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 5, 1965, 33-35,  
 and insert facing p. 24

TOPIC TAGS: titanium alloy, chromium alloy, molybdenum alloy, aluminum alloy,  
 metal physical property, metal hardness, metal aging

ABSTRACT: An attempt was made to find an aging treatment which gives maximum hard-  
 ness and strength. A series of  $\beta$ -alloys were selected for studying structure and  
 hardness as a function of aging temperature from 300 to 1000°C. The Ti alloys in-  
 vestigated varied in composition: Mo (1.6-7.9%), Cr (3.4-7.7%), Fe (3.1-6.1%) and  
 Al (3.2-3.6%). After due processing and heat treatment, the alloys were examined  
 by x-ray analysis, and Vickers hardnesses were measured. Both metallographic and  
 x-ray techniques showed  $\beta$ -solid solutions. All of the hardness data are given in

Card 1/4

L 57509-65

ACCESSION NR: AP5013155

0

fig. 1 of the Enclosure. The alloys were aged, after prior annealing and treatment, for one hour at temperatures ranging from 300 to 1000°C. The hardness shows a maximum around 500-550°C depending on the alloy. From 600-800°C the hardness gradually diminishes, and after 800°C an insignificant increase is noted in some alloys. All of the alloys have  $\beta$ -solid solution structures when aged at 300 and 400°C. A mixture of  $\alpha + \beta$  is noted after aging above 450°C, paralleling the increase in hardness. The maximum in hardness coincides with the greatest quantity of  $\alpha$ -phase, and upon further aging the quantity of  $\alpha$ -phase diminishes as does the hardness. At 800°C, all alloys revert to a  $\beta$ -solid solution.

TITLE: Investigation of alloys of the system Ti--Mo--Cr--Fe--Al

SOURCE: Soveshchaniye po metallokhimii, metallovedeniyu i primeneniyu titana i yego splavov, 6th. Novyye issledovaniya titanovykh splavov (New research on titanium alloys); trudy soveshchaniya. Moscow, Izd-vo Nauka, 1965, 89-91

TOPIC TAGS: titanium, iron, chromium, molybdenum, aluminum, titanium alloy, metal aging, annealing, hardness, x ray spectrum

ABSTRACT: The effect of annealing and aging on the hardness and x-ray spectra of alloys derived from the system Ti--Mo--Cr--Fe--Al was studied. The experimental procedure was described earlier by N. V. Ageyev, and L. A. Petrova (Dokl. AN SSSR, 1961, 138, No. 2, 359). Five different alloy compositions were studied, and the experimental results are presented graphically (see Fig. 1). Photographs of polished sections of the alloys annealed at different temperatures and aged for different periods of time are presented. The presence of satellite lines in the x-ray spectrograms are noted, but the authors refrain from giving an explanation for their presence. It is concluded that the alloys may prove interesting as low-alloy  $\beta$ -stabilizing high-strength titanium alloys.

TITLE: High-temperature thermomechanical treatment of  $\beta$ -alloy of the Ti-Mo-Cr-Fe-Al system

27 27 27 27 27

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 5, 1966, 12-14

TOPIC TAGS: thermomechanical treatment, titanium alloy, titanium beta alloy, molybdenum containing alloy, iron containing alloy, aluminum containing alloy, alloy thermomechanical treatment, alloy mechanical property, alloy structure

ABSTRACT: Forged specimens of complex titanium-base alloy containing 7%Mo, 5.5%Cr, 3%Fe, and 3%Al were subjected to high-temperature thermomechanical treatment (HTMT), rolled at 850, 950, and 1050C with a 20, 40, and 60% reduction in one pass and 80% in two passes, immediately water quenched, and then aged at 450C for 15 and 25 hr, at 500C for 5 and 10 hr, or at 525C for 5 hr. HTMT increased alloy strength without affecting ductility. For example, prior to aging the tensile strength of alloy hot rolled at 950C with a reduction of 20, 40, 60, and 80% was 96.5, 105.0, 96.7, and 99.5 kg/mm<sup>2</sup>, respectively, compared with 77.3 kg/mm<sup>2</sup> for alloy quenched from the same temperature without deformation. The corresponding figures for elongation were

ACC NR: AP6016583

2

16.6, 18.4, 17.7, and 18%, respectively, compared with 16.9%. The increased strength of the alloy after HTMT is explained by strain hardening and fragmentation of the  $\beta$ -alloy grains. Aging produced a further significant increase of strength. The best combination of strength and ductility was obtained after HTMT with 60—80% reduction at 850C and aging at 500C for 10 hr or 525C for 5 hr, after which the alloy had a tensile strength of 164—177 kg/mm<sup>2</sup>, an elongation of 4.5—9.0%, and a reduction of area of 8—15%. This effect of aging was found to result from the precipitation of the finely dispersed  $\alpha$ -phase. Orig. art. has: 3 figures and 1 table. [MS]

TITLE: Investigation of metastable  $\beta$ -alloys of the Ti-Mo-Fe-Al system

SOURCE: AN SSSR. Izvestiya. Metally, no. 1, 1966, 139-148

TOPIC TAGS: phase analysis, quaternary alloy, titanium base alloy, molybdenum, iron, aluminum, metal aging, mechanical property

ABSTRACT: This is a continuation of previous investigations (Ageyev, N. V., Rogachevskaya, Z. M. Zh. neorgan. khimii, 1959, IV, vyp. 10, 2323-2328; Ageyev, N. V., Grankova, L. P., Novik, P. K. Dokl. AN SSSR, 1962, 146, no. 2, 351-354) with the difference that it deals with Ti-Mo-Fe-Al alloys which quench to the  $\beta$ -solid solution, i.e. have an electron concentration of more than 4.20 el/at, but contain not more than 8.5% Fe and 8% Mo as well as 2.3 and 4% Al, and hence are of greater practical interest. Ingots of these alloys were melted by using a mixture of titanium sponge, Al-Mo master alloy, pure Al and armco iron. The ingots,

Card 1/2

UDC: 669.295

L 44354-66

ACC NR: AP6019834

weighing 400 g, were lathe-turned and subsequently hot-forged in an electric furnace at 1000-1100°C into rods of 15 mm diameter and squares measuring 15x15 mm. The forged alloys were annealed at 750 and 800°C for 1 hr and water-quenched. All the alloys quenched from 750°C had the  $\beta + \alpha$  phase structures, and all those quenched from 800°C, the structure of the  $\beta$ -solid solution, as was to be expected from their electron concentration. The forgings were milled in a milling machine and cut up into specimens for microstructural and radiographic examination as well as for tests of hardness and tensile strength. Measurements of the Vickers hardness of these alloys as a function of aging temperature (200-600°C) and time (1-100 hr) revealed that for most of the alloys hardness reaches its maximum (~500 kg/mm) after 10-25 hr at any aging temperature within the limits considered and thereafter remains virtually constant for 100 hr.  $\beta$ -alloys containing 2% Al, when heated to 400-500°C, undergo decomposition with segregation of  $\omega$ -phase which gets transformed into  $\alpha$ -phase after 10 hr.  $\beta$ -alloys containing 3 and 4% Al undergo decomposition with segregation of  $\alpha$ -phase. Of the alloys of Ti + 7% Mo + 6% Fe + 2, 3 and 4% Al the best mechanical properties (tensile strength 160 kg/mm<sup>2</sup>, plasticity 7.0%) were displayed by the alloy with 3% Al aged at 525°C for 20 hr and subsequently cooled in air. Orig. art. has: 7 figures, 3 tables.

TITLE: Structural transformations in titanium alloys

SOURCE: Soveshchaniye po metallokhimii, metallovedeniyu i primeneniyu titana i yego splavov, 6th. Novyye issledovaniya titanovykh splavov (New research on titanium alloys); trudy soveshchaniya, Moscow, Izd-vo Nauka, 1965, 82-88

TOPIC TAGS: annealing, phase composition, alloy, titanium, titanium alloy, electron microscopy/ VT3-1 alloy, VT14 alloy, VT16 alloy, VT15 alloy, VT10 alloy

ABSTRACT: The structural transformations induced by annealing in ( $\alpha + \beta$ ) alloys of the types VT3-1, VT14, and VT16, in  $\beta$  alloy of VT15 and in  $\alpha$  alloy of VT10, containing an intermetalloidal strengthening agent, were studied. The study was carried out by means of electron microscopy. Electron microscope photographs of specimens annealed at different temperatures are presented. Annealing alloys under different conditions leads to a phase transformation in the alloys. The optimum phase composition that possesses maximum strength and plasticity was found to consist of single  $\alpha$ -phase regions and highly dispersed heterogeneous ( $\alpha + \beta$ ) phase regions resulting from the decomposition of the metastable  $\beta$ -phase. Thermal stability of alloys may be increased by the addition of aluminum to the alloy. Orig. art. has: 2 figures.

TITLE: Method for the Determination of Yield Points During Torsion

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol. 26, No. 8,  
pp. 1006 - 1008

TEXT: The author suggests a new method for determining the yield points during torsion, which is based upon the hypothesis of similarity between torsion and tension diagrams and which corresponds to the modern plasticity theory. According to this hypothesis, the tangential stresses  $\tau$  and the displacements  $\gamma$  during torsion, interact with the normal stresses  $\sigma$  and the corresponding elongation  $\epsilon$  such that

$$\tau = \lambda \sigma$$

$$\gamma = \psi \epsilon \quad (1)$$

with  $\lambda$  denoting the tension coefficient and  $\psi$  the deformation coefficient. The values of the coefficients depend on the theory of strength. For the determination of the yield point by the method suggested, the sample is gradually loaded by a torsion moment. The torsion angle of each stage is then measured by a tensometer, and the test diagram is

Card 1/2

Method for the Determination of Yield  
Points During Torsion

S/032/60/026/008/034/046/XX  
B020/B052

plotted in the coordinates  $M - \gamma_r$  ( $\gamma_r = \theta r$ ). From this diagram, the torsional moment is determined. It corresponds to the proportionality limit of torsion and displacement, and also follows Hook's law. According to the hypothesis regarding the similarity of torsion and tension diagrams, the complete relative displacement  $\gamma_T$  corresponds to the yield point,

i.e.  $\gamma_T = \gamma_{rel}/\alpha_T$ , with  $\alpha_T$  denoting the material constant which can be calculated from the elongation tests. From the diagram  $M - \gamma$  (Fig.), the limit torsional moment  $M_T$ , and from it the yield point  $\tau_T$  are com-

puted. In determining the yield points by the method suggested the test curves for determining the quantity  $\tau$  cannot be graphically examined by the Ludwig equation nor by N. N. Davidenkov's method (see Fig.). The experiments proved the correctness of the relations obtained. There are 1 figure and 2 Soviet references.

TARASENKO, I. I.

*Failure Mechanisms of Metals*

1951 Tarasenko, I. I., On the condition of failure of metals in tension, *Zh. tekhn. fiz.* 21, 11, 1101-1111, Nov. 1951

To combine the generalized stress-strain curves for different methods of loading, author introduces the concept of a 'constant modulus of plasticity' for the equivalent state of stress, such as yield point, ultimate tensile strength, fracture, etc., by which he means that equivalent points of all curves lie on a single ray through the origin. Then he introduces the concept of a coefficient of consistency relating appropriate equivalent yield stress for each method of loading to the yield stress of the simple tension curve, and accepts this coefficient for the plastic part of the curve as constant. In his conclusions he assumes the uniformity of deviation of stress and strain rates, and the incompressibility of the metal. Author provides some experimental data which, in the author's opinion, do not supply an experimental support for his concepts.

TITLE: Ductility and Strength Criteria for Metals (Usloviya plastichnosti i prochnosti metallov)

PERIODICAL: Nauch. tr. Leningr. inzh.-stroit. in-ta, 1956, Nr 23, pp 102-113

ABSTRACT: Ductility and strength criteria are proposed in the form of a linear relationship between the greatest tangential stress and the mean normal stress. It is noted that such a criterion was proposed earlier by N. N. Davidenkov (Vestn. inzh. i tekhnikov, 1947, Nr 4). From the experimental data adduced the author concludes that the said criterion yields better results than an analogous criterion which in lieu of the greatest tangential stress employs the magnitude of the intensity of the stresses. The author also proposes a refinement of the criterion relative to the effect of the stress deviation parameter. Ultimately the relationship

$$\sigma_1 = \sigma_{\max} + k_s + f_s \sin \pi \alpha$$

Card 1/2

124-57-2-2-32

### Ductility and Strength Criteria for Metals

is obtained, where  $t_{\max}$  is the greatest tangential stress,  $s$  is the mean normal stress,  $\mu$  is the Lode stress parameter, and  $t_1$ ,  $k$ , and  $\ell$  are constants. The correction contained in the last term of the formula is introduced by the author on the basis of the well-known diagram for the cessation of the similarity between the stress and deformation deviators. The concepts manipulated by the author at this point remain incomprehensible. Theoretically it is impossible to establish a connection between the cessation of the similarity between the deviators and the resistance to deformation, yet the author fails to provide any experimental substantiation.

TITLE: Concerning Plasticity and Strength Criteria for Metals (K voprosu o kriteriyakh plastichnosti i prochnosti metallov)

PERIODICAL: Zap. Leningr. gorn. in-ta, 1956, Vol 33, Nr 3, pp 109-116

ABSTRACT: The authors examine two plasticity criteria: 1) The maximum tangential stress is a function of the mean hydrostatic stress, and 2) the octahedral stress is a linear function of the mean hydrostatic stress. To find the linear function in either case, one needs only to know the yield point of the material in tension and compression; one is then able to calculate the yield point in torsion. It emerges that adoption of the first-named criterion yields results that agree with the experimental findings of the present authors and with those of other investigators, whereas adoption of the second leads to an overrating of the yield point of the material in torsion.

PERIODICAL: V sb.: 15-ya nauchn. konferentsiya Leningr. inzh. -stroit. in-ta. Leningrad, 1957, pp 382-386

ABSTRACT: Justification of the possibility of a considerable increase in the standards of permissible stresses is given for eccentric compression and tension of beams manufactured out of plastically deforming materials when calculated not according to their ultimate strength but nominally according to their elastic stage of deformation. Expressions are offered for coefficients that enable one to convert the permissible stresses for simple compression or simple tension into nominally permissible stresses under eccentric tension and eccentric compression. These coefficients were obtained from the factual curvilinear deformation diagrams of the material in the elastic-plastic zones and also approximately by the

TITLE: Strength of steel in complex stressed states in case of simple and complex courses of loading

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 7, 1962, 31, abstract 71180  
(In collection: "Issled. po uprugosti i plastichnosti", I. L. Leningr. un-t, 1961, 205 - 212)

TEXT: Strength characteristics of tube samples of steel 3 were investigated at simple and complex courses of loading in biaxial tension. The rated real stresses and deformations were determined by equations of the theory of maximum normal stress and maximum relative elastic elongation, maximum tangential stress, and the theory by Huber-Mises. At simple loading the course of loading in the axes  $\sigma_z - \sigma_\theta$  coincides with the radius starting from the origin of coordinates at certain angles  $\theta(\sigma_z/\sigma_\theta = \text{tg } \theta = \text{const})$ . The complex loading occurred in two ways: a) course  $\sigma_\theta = \sigma_z$  passed up to a definite load, and diverged in different sides of the line  $\sigma_\theta = \sigma_z$  perpendicularly to it until rupture; b) the

Card 1/2

Strength of steel in...

S/137/62/000/007/0-2/072  
AC57/A101

first part of the course passed along the line  $\sigma_1 = 0$  or  $\sigma_2 = 0$  up to a certain load, after which another stress was increased at constant  $\sigma_1$  or  $\sigma_2$ . At the investigated courses if complex loading the strength of the steel decreased by 5.5% in comparison to the strength at simple loading; at simple loading the experimental data are in better agreement with Sen-Vennan conditions of plasticity than with Mises conditions; the shape of the curves  $\sigma_1 = \sigma_1(\epsilon_1)$  depends upon the course of loading. TITLE: Concerning the stability of compressed columns made of brittle and plastic materials.

PERIODICAL: Referativnyy zhurnal, Mekhanika, no. 4, 1963, 25, abstract 4V199  
(Stroitel. mekhan. i raschet sooruzh., no. 5, 1962, 24-27)

TEXT: The author adduces familiar formulas for the critical loading of a central compressed hinge-supported column of constant cross-section, the material of which possesses various moduli for loading and for no load. With values of the critical stresses close to the yield limit (in brittle materials, the breaking stress), the author recommends the use of the relation  $s$  (epsilon) instead of  $\sigma$  (epsilon), where  $s$  is the true stress,  $\sigma$  is the conditional stress computed for the initial area of the transverse cross-section, epsilon is the conditional (not logarithmic) deformation. By this method the critical flexibility is computed which corresponds to the yield limit, for a material with clearly marked yield range. This flexibility turns out to be approximately equal to  $\pi$  - this being 15-20 times less than the empirical values for low-carbon steel of type St-3. B. M. Broude.
